#### ABSTRACT

Technology is needed in every industry because it can simplify the production process, improve production quality, and enhance the company's reputation in the sight of consumers. The cylinder counting activity at PT Batuah Energi Indonesia is still done manually, involving time and standardized estimation of LPG cylinder loads, which faces inaccuracy issues. In fact, PT Batuah Energi Indonesia has facilities that handle many LPG cylinders from various users and providers of LPG cylinders. While accurate cylinder counts are beneficial to the industry, companies need technology that can automatically calculate the number of filled LPG cylinders. Therefore, this study was carried out to demonstrate to students how to develop automatic tube counters using an infrared E18-D80NK as a tube detector, NodeMCU microcontrollers ESP8266 as controllers, Arduino IDE for developing programs, and IoT for remote monitoring. The developed device approach, specifically using the E18-D80NK infrared proximity sensor based on the NodeMCU ESP8266, can be coded using the Arduino IDE compiler. For the detection of the number of tubes, the E18-EN80K infrared sensor is used and data transmission wirelessly utilizes the Blynk application. The results of the automatic tube counter monitoring tool were successfully tested with a 100% accuracy rate, utilizing the E18-D80NK infrared sensor and NodeMCU microcontroller ESP8266, and can be monitored remotely using Blynk.

Keywords: E18-D80NK infrared sensor, internet of things, LPG tube calculation, NodeMCU ESP8266.

#### I. INTRODUCTION

Patuah Energi Indonesia LPG Bulk Filling Station (SPBE), located on Trans Kalimantan, East Kapuas, is a private company that assists PT Pertamina (Persero) in managing LPG gas by filling and distributing LPG gas tube to the public. LPG stands for Liquefied Petroleum Gas. LPG is a hydrocarbon gas produced by oil and gas refineries along with the main components of propane and butane gas. LPG gas is a fuel derived from natural gas found in the earth and has been processed so that it can be used by the community. This innovation aims to diversify natural resources in Indonesia, so that people do not only depend on one type of fuel.

The presence of technology in the industrial world is very important for every company to facilitate the production process. One of the related aspects is the calculation of the amount of filling tube production that will be distributed to the community from the PT Batuah Energi Indonesia SPBE workshop area. The production process carried out in the workshop area is the process of unloading or lowering the tube to the conveyor, the filling process, the batting process or closing the tube, the wrapping process or tube sealing, and finally the process of loading or entering the tube into the fleet that can be distributed. From this process, calculating the number of filled tubes can be done with a manual counting tool or hand tally counter applied to the wrapping path to the loading area at PT Batuah Energi Indonesia SPBE workshop [1].

In general, in some companies, especially in SPBE, PT Batuah Energi Indonesia still uses manual methods in the calculation process. PT Batuah Energi Indonesia has a workshop or filling hall that

accommodates many consumer tubes from various local areas. This process is inefficient because it involves calculating production quantities manually, increasing the risk of human error such as employee inaccuracy in calculating the number of tubes to be loaded. The manual approach also poses a number of drawbacks, including the considerable time required, the risk of fatigue in the person performing the calculation, and the inaccuracy of the calculation results. To overcome these challenges, companies require the use of automated counting systems [2], [3].

There are several solutions proposed in research related to automatic number counting systems. First, there is "Automatic Goods Counter Tool Using Arduino Uno-Based Infrared Sensor" by Husain et al. in 2020 [4]. The second is "Visitor Counter Tool Based on NodeMCU Esp8266 and Telegram Application Bot" by Ahmad Fauzan in 2022 [5]. The third is "Prototype Conveyor Material Counter Based on Arduino Uno Microcontroller" by Susanto in 2020 [6]. Their research involved evaluating the infrared sensor and the HC-SR04 ultrasonic sensor, with a comparison to manual measuring instruments [7], [8]. The infrared sensor reading results show an insignificant difference with the reading results from the manual calculation measuring instrument, indicating that the infrared sensor is reliable as a number reader [9]. These studies can be used as references for the development and improvement of tools that will be implemented at PT Batuah Energi Indonesia.

This article, "Automatic Tube Counter Monitoring System Using Infrared-Based Sensor NodeMCU ESP826 At SPBE PT Batuah Energi Indonesia" is an innovation for implementing an automatic number counters system explained in [10]. It is expected that these tools will assist and facilitate workers in an industry and a company agency in calculating the tubes they have produced in large quantities, improving production quality, minimizing errors in a manual calculation, and making company activities effective and efficient as an answer of the problem described in [11].

Based on the description above, the problem raised in this project task is to design an automatic tube counter monitoring system using an infrared sensor based on NodeMCU ESP8266. The objectives of this project include the application of the E18-D80NK type infrared sensor as a tube detection device that moves through it [12]. In addition, the project also addresses the implementation of the NodeMCU ESP8266 microcontroller as a controller, receiver, and data processor in an automatic LPG cylinder counter electronic system [13], [14]. Furthermore, the project work covers the application of IoT (Internet of Things) technology for automatic LPG cylinder counter monitoring using the Blynk platform [15].

The purpose of this project entitled "Automatic Tube Counter Monitoring System Using Infrared Sensor Based on NodeMCU ESP8266 at SPBE PT Batuah Energi Indonesia" is to design an automatic tube counter monitoring system by utilizing an infrared sensor based on NodeMCU ESP8266. This project aims to apply the E18-D80NK type infrared sensor as a tube detection device that moves through it [16]. In addition, this project also aims to apply the NodeMCU ESP8266 microcontroller as a controller, receiver, and data processor in an automatic LPG cylinder counter electronic system. The application of IoT (Internet of Things) is expected to facilitate the monitoring of the automatic cylinder counter using the Blynk platform.

#### II. RESEARCH METHOD

The development research methodology used in this study involves the process of creating new products or systems based on existing scientific knowledge. In this specific case, the research aims to develop an automatic tube counter using an infrared sensor, specifically the NodeMCU-based ESP8266, for monitoring systems at SPBE PT Batuah Energi Indonesia. This system will incorporate three push buttons and LED indicators for control and feedback. The core functionality of this automatic tube counter relies on the operation of infrared (IR) sensors. These sensors are programmed to automatically count the number of tubes passing through them by detecting their presence. They accomplish this by obstructing the IR sensors' light beam, which triggers the counting mechanism. The three push buttons provided will enable specific functions such as stopping, continuing, or resetting the count, while the LED indicators will visually communicate different statuses or actions within the system.

To achieve its objectives, this research utilizes a set of materials and tools that have been specifically described. Some of the components used include an acrylic box measuring 14.5 cm x 9.5 cm x 5 cm, a

Figure 1. Design cover front section of automatic tube counting device and design cover side section of automatic tube counting device

Figure 2. System tool layout planning Monitoring automatic tube counter at SPBE PT Batuah Energi Indonesia

16 mm push button, a 5 mm LED holder, jumper cables, an aviation plug (3 Pin 12 mm metal GX 12-3), a USB data cable (type B), a female DC power plug (2.1 mm), a 5x37 cm PCB board, and tin. In addition, the tools used involve a laptop or PC, Infrared Proximity Sensor E18-D80NK, NodeMCU ESP8266, Blue LCD I2C 20 x 4, DC Stepdown LM 2596, 5 mm red, yellow, and green LEDs, 12VDC power supply, switch, 6-30V DC motor, and soldering tools. The use of these materials and tools is essential for the execution of the experiments and the development of the intended project.

This study focuses on the creation of an automatic tube-counting device utilizing the NodeMCUbased infrared proximity sensor E18-D80NK and the ESP8266 microcontroller. The objective is to engineer a device capable of accurately counting the number of tubes automatically. The development of this tool encompasses two fundamental procedures: the design of the automatic tube counting device and the design of the associated program for tube counting. These two key processes work in tandem to achieve the desired functionality, where the device's hardware and software components are meticulously designed to ensure precise and efficient tube counting.

#### A. Automatic Tube Counter Design

The automatic tube counter, employing the infrared proximity sensor E18-D80NK, was conceptualized using microcontroller software that incorporated the form menu within the insert option. However, the progression of this research encountered delays due to the company's circumstances in fabricating conveyor lines, hindering the direct implementation of the tool. Despite this setback, the design process resulted in the creation of two distinctive designs: the prototype design (depicted in Figure 1) and the intended design for implementation at PT Batuah Energi Indonesia (illustrated in Figure 2). Both designs

Figure 3. System suite of tools Monitoring Counter Uses Fritzing Software

serve as reference points for deploying automatic tube count counters. The primary aim of this tool is to test an automatic tube counting system utilizing the infrared proximity sensor E18-D80NK. The forthcoming design of the tool is delineated as follows, building upon the groundwork laid out in these initial prototype and proposed implementation designs.

The implementation of the automatic tube counter monitoring system using the NodeMCU-based infrared sensor ESP8266 at SPBE (Fuel Filling Station) PT Batuah Energi Indonesia involves strategic planning for its placement. This system will be positioned at key locations within the facility to effectively monitor and count the tubes or objects passing through these points. The planning process includes determining the optimal spots for installing the infrared sensors, considering factors such as traffic flow, visibility, and accuracy in tube counting. The goal is to ensure the sensors are situated in locations where they can efficiently detect and count the tubes, contributing to a reliable and accurate monitoring system at PT Batuah Energi Indonesia's SPBE.

#### B. Automatic Tube Counting Program Design

The wiring design planning for the automatic tube counter monitoring system using the NodeMCU ESP8266-based infrared sensor was created utilizing Fritzing software. This software enables the easy assembly and visualization of the components required for the counter monitoring system. In Figure 3, the design showcases the schematic layout of the series of tools that are planned to be created for this system. It illustrates the arrangement and connections of the NodeMCU ESP8266, the infrared sensor, and other components necessary for the automatic tube counter. This visual representation aids in understanding the wiring and connections, facilitating the construction and implementation of the automatic tube counter monitoring system.

The component that functions as an output in this tool is the LED, which will display a color display as a notification whenever the tube is detected by the infrared sensor. Meanwhile, the push button component acts as an input. To make the tube counter tool, 3 push buttons with different functions are needed, namely the reset, stop, and continue buttons. When the reset button is pressed, the count will be reset to 0. If the stop button is pressed, the counting process will stop so that the tube passing through the infrared sensor will not be detected. Meanwhile, if the continue button is pressed, the sensor will read the tube that passes through the sensor and the counting process will continue. The components are connected to the NodeMCU pins according to the configuration shown in Table 1, which includes the NodeMCU ESP8266 pin settings with the infrared sensor. Table 2 describes the pin configuration of the NodeMCU ESP8266 with the 12C LCD, while Table 3 describes the pin configuration of the NodeMCU ESP8266 with the button & LED.

Figure 4. Automatic tube counting program design.

The program designed for the automatic tube counting device utilizes the infrared proximity sensor E18-D80NK and is created using the C++ programming language within the Arduino IDE software. This program is specifically tailored to operate the system responsible for counting tubes automatically. It involves writing code in C++ using the Arduino Integrated Development Environment (IDE) to control and process data received from the E18-D80NK infrared sensor, enabling accurate tube counting functionalities. The program's design encompasses algorithms and instructions written in C++ to interact with the sensor, process its input, and accurately count the tubes passing through the system. This program forms the core intelligence behind the automatic tube counting device, ensuring its efficient and precise operation.

In order to create a program for an automatic tube counter using the E18-D80NK infrared proximity sensors with the Arduino IDE software, the C++ programming language is utilized. The Arduino IDE, an open-source platform, facilitates the development of the program to enable the microcontroller to effectively respond to the data received from the infrared sensors. This program is intended to manage

Figure 5. Flowchart system monitoring automatic tube counter.

the detection and counting of objects passing through the sensors. By leveraging the Arduino IDE and its compatibility with the E18-D80NK sensors, the aim is to create a functional and accessible solution for automatic tube counting, allowing for ease of use by individuals leveraging the open-source nature of the software.

A flowchart provides a visual representation of the sequence of actions, decisions, and processes within a system, aiding in understanding the system's functionality and operation. The specific details of Figure 5's flowchart would likely illustrate the step-by-step processes involved in the automatic tube counting system, possibly detailing the sensor readings, counting mechanisms, decision points, and output actions.

The flowchart for the main procedure of the automatic tube counter tool initiates an initialization process for the LCD and Wi-Fi signal search, establishing a connection to the NodeMCU. Once linked, the tube counting process begins. The NodeMCU executes the programmed instructions, primarily involving the infrared sensor inputs. These sensors, labeled as sensor 1 and sensor 2, function to detect

Figure 6. Prototype of automatic conveyors and counting devices.

the passing objects. When sensor 1 to sensor 2 identifies an object, the count increases by 1; when sensor 2 to sensor 1 reads an object, the count decreases by 1. The results of input and output data management display on the LCD and Blynk in real-time, employing the push button function. Pressing the stop button activates the red LED and halts the sensor readings. Pressing it again deactivates the red LED, allowing the sensor to resume object detection. The reset button triggers the yellow LED briefly and resets the tube count to zero on both the LCD and Blynk displays. This comprehensive process details the systematic operations and functionalities involved in the automatic tube counting tool.

The Standard Operating Procedures (SOP) for the automatic tube counting tool utilizing the E18-D80NK infrared proximity sensors with NodeMCU ESP8266 are outlined as follows.

- 1. Calculation Timing: The counting occurs post the tube wrapping or final sealing process, marking tubes ready for dispatch.
- 2. Sensor Placement and Data Input: Two infrared sensors (E18-D80NK) are situated along the one-way conveyor area for tube loading, detecting tubes as objects. When an object is detected, the sensors relay data input to the NodeMCU ESP8266.
- 3. Increment Counting (Incoming Sensor): If infrared sensor A detects the first object and then infrared sensor B detects the second object, termed the incoming sensor, the count value increases by one.
- 4. Decrement Counting (Reverse Sensor): If infrared sensor B detects the first object and then infrared sensor A detects the second object, known as the reverse sensor, the count value decreases by one.
- 5. Display Readings: Readings taken by the E18-D80NK sensors are displayed on the 20 x 4 LCD and depicted on Blynk when successful.
- 6. Pausing Reading Process (Stop Button): Upon pressing the stop button, the sensors cease calculating passing objects. A bright red LED indicates the pause, while the 20 x 4 LCD and Blynk display the last recorded data.
- 7. Resuming Reading Process (Continue Button): Pressing the continue button reactivates the sensors to resume calculating passing objects. The red LED turns off, and the 20 x 4 LCD and Blynk display the latest data.
- 8. Reset Functionality: Initiating the reset button sets the count to zero. A yellow LED lights up briefly, signifying a reset, and the 20 x 4 LCD display and Blynk exhibit data from the initial count.

These SOPs provide a comprehensive guideline for the functioning and operation of the automatic tube counting system, defining the processes triggered by sensor readings and button inputs, as well as how the data is displayed and managed through various control mechanisms.

#### III. RESULTS AND DISCUSSION

The findings of this study are prototypes of conveyors and automatic counting equipment. Figure 6 shows an illustration of the prototype and the tool. Following the results of the prototype conveyor and automatic counting device, the following tests were performed. The first test involves comparing the readings of the E18-D80NK infrared proximity sensor to push buttons, a 20 x 4 LCD, Blynk data, and LED indications. The test results are shown in Table 4.

TABLE 4							
TESTING THE RESPONSE OF COMPONENTS TO INFRARED PROXIMITY SENSOR READINGS							
No	Push Button	Component Response					
	Stop	LCD 20 x 4	Active				
1		Data Blynk	Active, no data changes				
		Indicator LED	Red LED is active				
		Infrared sensor A to B	Active, does not read objects				
		Infrared sensor B to A	Active, does not read objects				
2	Continue	LCD 20 x 4	Active				
		Data Blynk	Active, data changes in real time				
		Indicator LED	Red LED is not active				
		Infrared sensor A to B	Active, reading objects				
		Infrared sensor B to A	Active, reading objects				
3	Reset	LCD 20 x 4	Active				
		Data Blynk	Active, changes data to zero				
		Indicator LED	Yellow LED is active				
		Infrared sensor A to B	rared sensor A to B Active, reads the object from the beginning				
		Infrared sensor B to A	Active, reads the object from the beginning				

TABLE 5							
CALCULATED RESPONSE TESTING TO INFRARED PROXIMITY SENSOR READINGS							
Infrared sensor	Test	Manual	Automatic	Accuracy Percentage			
	1	10	10	100%			
	2	20	20	100%			
	3	30	30	100%			
	4	40	40	100%			
Infrared consorr A to D	5	50	50	100%			
Infrared sensor A to B	6	60	60	100%			
	7	70	70	100%			
	8	80	80	100%			
	9	90	90	100%			
	10	100	100	100%			
	1	10	10	100%			
	2	20	20	100%			
	3	30	30	100%			
Infrared sensor B to A	4	40	40	100%			
	5	50	50	100%			
	6	60	60	100%			
	7	70	70	100%			
	8	80	80	100%			
	9	90	90	100%			
	10	100	100	100%			

The second test results are shown in Table 8. The test was carried out by comparing the detection state of infrared proximity sensors A and B. The output of this sensor reading is data with the following conditions.

1. When infrared proximity sensor A detects an object, and subsequently infrared proximity sensor B detects an object, the computed value + 1 is used to identify this sensor as an entry sensor.

2. When infrared proximity sensor B detects an object, infrared proximity sensor A detects an object, and the computed value is -1, this sensor is referred to as a reverse sensor.

Furthermore, Figure 7 shows how the components are integrated and set up within a casing box and utilized in a real-world setting, demonstrating the practical application of the automatic tube counting system. Part A is the part which includes the essential components housed within a casing box. It comprises the NodeMCU ESP8266, jumper cables, LM 2596 step-down module, I2C LCD, push buttons, LEDs, and a PCB board. The arrangement and integration of these components likely form the core of the counting system. Part B represents the practical implementation of the tool. It features a conveyor system equipped with two infrared sensors used to detect and calculate the quantity of passing tubes. Additionally, there is a display for indicating the tube count and LEDs used to show the status of various push buttons (stop, reset, and continue functions).

Figure 7. Views of the automatic tube counting tool from the inside and outside

Figure 8. Display the number of counting tubes on the Blynk application and display on the LCD when testing is carried out.

Figure 8 illustrates the Blynk display scenarios and LCD display. These scenarios would present the graphical interface's responses when different push buttons (stop, continue, reset) are activated. They provide visual feedback or information on the Blynk application, giving users insights into the operational states and actions of the automatic tube counting system. Figure 8A represents the Blynk application displaying the status or notification when the stop button is activated. It includes information or indications about the pausing of tube counting, showing a specific message or status denoting the system is in a paused state. Figure 8B reflects the Blynk application response when the continue button

is activated. It exhibits information or indications of resumed tube counting, displaying a distinct message or status showing the system is back in an active counting state. The Blynk display reaction after pushing the reset button is shown in Figure 8C. It displays information or notifications about the reset action, such as a message or a status indicating that the counting has been reset to zero.

The research referenced in [4] has implemented an automatic counting system using one infrared sensor and a reset button. In contrast, the current study features an enhanced system utilizing two infrared sensors and three buttons. By introducing dual sensors and an extended control interface through multiple buttons, the system design in this study offers advantages in accuracy, reliability, and functionality compared to the previous system described in reference[4]. The use of three different buttons (reset, stop, and start) provides better control over sensor readings and calculation results. The combination of the E18-D80NK sensor's superior infrared light range with the precise control provided by the three different buttons, contributes to an efficient and flexible automatic counting system. This setup enables higher accuracy in object detection while providing users with better control and management of the counting process. In reference research [12], a 16x2 LCD panel and IoT display via a website were used. However, the current study uses a 20x4 LCD, which provides a larger display area. The use of a 20x4 LCD in this study allows for more complete and detailed information, such as quantity, time, and date. In addition, the application of Blynk for IoT monitoring provides easily accessibility of the system.

#### IV. CONCLUSION

The conclusion that can be drawn from the data above is that the automatic tube counter monitoring system tool has been successfully made with an accuracy rate of 100%, using an infrared sensor based on NodeMCU ESP8266. The E18-D80NK infrared sensor is effectively used as a tube detector that moves past the sensor. The NodeMCU ESP8266 microcontroller is proven to function well in the automatic tube counting system as a controller, receiver, and data processor. The application of Blynk is successfully used to implement the Internet of Things (IoT) as a tube counter monitoring system. As a suggestion for future research development, it is recommended to consider the use of a printed PCB board for this counting device circuit. This will ensure more organized placement of components, reduce wiring requirements, and develop more efficient electrical pathways. The purpose of using a printed PCB is to prevent undesirable results and facilitate the process of repairing or replacing components.

There are still some shortcomings in the implementation of research and the preparation of this thesis report. For further research development, especially related to the counter circuit, it is recommended that researchers use printed PCB boards. The use of printed PCBs will help the arrangement of components to be more structured, reduce the use of cables, and create more efficient electrical pathways. The goal is to prevent the possibility of various undesirable events while simplifying the process of repairing or replacing components.

In the future, it is recommended to develop this tool not only in terms of counting the number of tubes, but also to include other features that can improve its functionality. Some development suggestions include the ability to calculate the weight of the filled canister and include features to classify canisters based on their capacity, such as 3 kg or 5 kg canister classes.
